

Now let me explain the **app/project flow** first (understand this before coding).

Think of BudgetWise like this

Imagine your father or a shop owner wants to track daily spending.

Instead of writing in a notebook, your Python app does it.

The app has **3 jobs**.

Job 1 → Take expense from user

User says:

I spent ₹500 on Food

Your program asks:

Enter Amount: 500

Enter Category: Food

Now program stores it temporarily.

Job 2 → Save expense permanently

If program closes, data should not disappear.

So you save:

500,Food

inside:

expenses.txt

Now even after closing program:

data remains safe

Job 3 → Analyze spending

Suppose file has:

500,Food
300,Travel
1000,Rent
200,Shopping

Now user wants answers.

Program calculates:

Total spent = 2000

Average expense = 500

Highest expense = 1000

Lowest expense = 200

This is where **NumPy** comes.

Full App Flow (Important)

START PROGRAM

SHOW MENU

1 Add Expense
2 View Expenses
3 Analyze Expenses
4 Exit

User chooses option

If 1:

Take amount + category
Save in file
Return to menu

If 2:

Read file
Display all expenses
Return to menu

If 3:
Read amounts
Convert into NumPy array
Calculate analytics
Return to menu

If 4:
Stop program

How I want you to think while building

Do NOT think:

I need to build the whole project.

Think:

Step 1

Can I make menu repeat forever?

If yes → next.

Step 2

Can I take amount/category input?

If yes → next.

Step 3

Can I save it in file?

If yes → next.

Step 4

Can I read file and display data?

If yes → next.

Step 5

Can I extract numbers for NumPy?

If yes → next.

Step 6

Can I analyze with NumPy?

If yes → done.

Architecture in your brain

Split app into 4 functions.

main_menu()

add_expense()

view_expenses()

analyze_expenses()

Then connect everything.

Think of each function as **one worker doing one job**.

My one rule for you

Build ugly first.

Do NOT try:

- perfect code
- advanced OOP
- beautiful structure

First make it work.

Bad code that works > Beautiful code that doesn't exist.
